

# Package ‘sdcMicro’

December 22, 2014

**Type** Package

**Title** Statistical Disclosure Control methods for anonymization of microdata and risk estimation

**Version** 4.4.0

**Date** 2014-07-18

**Author** Matthias Templ, Alexander Kowarik, Bernhard Meindl

**Maintainer** Matthias Templ <matthias.templ@gmail.com>

**Description** Data from statistical agencies and other institutions are mostly confidential. This package can be used for the generation of anonymized (micro)data, i.e. for the creation of public- and scientific-use files. In addition, various risk estimation methods are included. Note that the package sdcMicroGUI includes a graphical user interface for various methods in this package.

**LazyData** TRUE

**ByteCompile** TRUE

**LinkingTo** Rcpp

**Depends** R (>= 2.10), brew, knitr,data.table,xtable

**Suggests** laeken

**Imports** car, robustbase, cluster, MASS, e1071, tools, Rcpp, methods,sets

**License** GPL-2

**URL** <https://github.com/alexkowa/sdcMicro>

|------------------|---|
| sdcMicro-package | <i>Statistical Disclosure Control (SDC) for the generation of protected microdata for researchers and for public use.</i> |
|------------------|---|

---

## Description

This package includes all methods of the popular software mu-Argus plus several new methods. In comparison with mu-Argus the advantages of this package are that the results are fully reproducible even with the included GUI, that the package can be used in batch-mode from other software, that the functions can be used in a very flexible way, that everybody could look at the source code and that there are no time-consuming meta-data management is necessary. However, the user should have a detailed knowledge about SDC when applying the methods on data.

The package is programmed using S4-classes and it comes with a well-defined class structure.

The implemented graphical user interface (GUI) for microdata protection serves as an easy-to-handle tool for users who want to use the sdcMicro package for statistical disclosure control but are not used to the native R command line interface. In addition to that, interactions between objects which results from the anonymization process are provided within the GUI. This allows an automated recalculation and displaying information of the frequency counts, individual risk, information loss and data utility after each anonymization step. In addition to that, the code for every anonymization step carried out within the GUI is saved in a script which can then be easily modified and reloaded.

## Details

Package: sdcMicro  
 Type: Package  
 Version: 2.5.9  
 Date: 2009-07-22  
 License: GPL 2.0

## Author(s)

Matthias Templ, Alexander Kowarik, Bernhard Meindl  
 Maintainer: Matthias Templ <templ@statistik.tuwien.ac.at>

## Examples

```
## example from Capobianchi, Polettini and Lucarelli:
data(franmdat)
f <- freqCalc(franmdat, keyVars=c(2,4,5,6),w=8)
f
f$fk
f$Fk
## with missings:
x <- franmdat
x[3,5] <- NA
x[4,2] <- x[4,4] <- NA
x[5,6] <- NA
x[6,2] <- NA
f2 <- freqCalc(x, keyVars=c(2,4,5,6),w=8)
f2$Fk
## individual risk calculation:
```

```

indivf <- indivRisk(f)
indivf$rk
## Local Suppression
localS <- localSupp(f, keyVar=2, indivRisk=indivf$rk, threshold=0.25)
f2 <- freqCalc(localS$freqCalc, keyVars=c(2,4,5,6), w=8)
indivf2 <- indivRisk(f2)
indivf2$rk

## select another keyVar and run localSupp once again,
## if you think the table is not fully protected
data(free1)
f <- freqCalc(free1, keyVars=1:3, w=30)
ind <- indivRisk(f)
## and now you can use the interactive plot for individual risk objects:
## plot(ind)

## Local suppression with localSupp2 and localSupp2Wrapper is more effective:
## example from Capobianchi, Polettini and Lucarelli:
data(francdat)
l1 <- localSuppression(francdat, keyVars=c(2,4,5,6), importance=c(1,3,2,4))
l1
l1$x
l2 <- localSuppression(francdat, keyVars=c(2,4,5,6), k=2)
l3 <- localSuppression(francdat, keyVars=c(2,4,5,6), k=4)
## long computation time:
## l = localSupp2(free1, keyVar=1:3, w=30, k=2, importance=c(0.1,1,0.8))

## we want to avoid missings in column 5:
#l1 <- localSupp2Wrapper(francdat, keyVars=c(2,4,5,6), importance=c(1,1,0,1),
#  w=8, kAnon=1)
#l1$x
## we want to avoid missings in column 5 and allow missings in 1 only if
## is really necessary:
#l1 <- localSupp2Wrapper(francdat, keyVars=c(2,4,5,6), importance=c(0.1,1,0,1),
#  w=8, kAnon=1)
#l1$x
#plot(l1)

## Data from mu-Argus:
## Global recoding:
data(free1)
free1[, "AGE"] <- globalRecode(free1[, "AGE"], c(1,9,19,29,39,49,59,69,100), labels=1:8)

## Top coding:
topBotCoding(free1[, "DEBTS"], value=9000, replacement=9100, kind="top")

## Numerical Rank Swapping:
## do not use the mu-Argus test data set (free1)
# since the numerical variables are (probably) faked.
data(Tarragona)
Tarragona1 <- rankSwap(Tarragona, P=10)

## Microaggregation:

```

```

m1 <- microaggregation(Tarragona, method="onedims", aggr=3)
m2 <- microaggregation(Tarragona, method="pca", aggr=3)
# summary(m1)
## approx. 1 minute computation time
# valTable(Tarragona, method=c("simple", "onedims", "pca"))

data(microData)
m1 <- microaggregation(microData, method="mdav")
x <- m1$x ### fix me
summary(m1)
plotMicro(m1, 0.1, which.plot=1) # too less observations...
data(free1)
plotMicro(microaggregation(free1[,31:34], method="onedims"), 0.1, which.plot=1)

## disclosure risk (interval) and data utility:
m1 <- microaggregation(Tarragona, method="onedims", aggr=3)
dRisk(obj=Tarragona, xm=m1$mx)
dRisk(obj=Tarragona, xm=m2$mx)
dUtility(obj=Tarragona, xm=m1$mx)
dUtility(obj=Tarragona, xm=m2$mx)

## S4 class code for Adding Noise methods will be included
#in the next version of sdcMicro.

## Fast generation of synthetic data with aprox.
#the same covariance matrix as the original one.

data(mtcars)
cov(mtcars[,4:6])
cov(dataGen(mtcars[,4:6],n=200))
pairs(mtcars[,4:6])
pairs(dataGen(mtcars[,4:6],n=200))

## PRAM

set.seed(123)
x <- factor(sample(1:4, 250, replace=TRUE))
pr1 <- pram(x)
length(which(pr1$xpramed == x))
x2 <- factor(sample(1:4, 250, replace=TRUE))
length(which(pram(x2)$xpramed == x2))

data(free1)
marstatPramed <- pram(free1[, "MARSTAT"])
## Not run:

sdc@risk$model

## End(Not run)

```

---

addNoise

---

*Adding noise to perturb data*

---

## Description

Various methods for adding noise to perturb continuous scaled variables.

## Usage

```
addNoise(obj, variables, noise=150, method="additive", ...)# ,p, delta)
```

## Arguments

|           |   |
|-----------|---|
| obj       | either a data frame, matrix or a sdcMicroObj that should be perturbed               |
| variables | vector with names of variables that should be perturbed                             |
| noise     | amount of noise (in percentages)  |
| method    | choose between 'additive', 'correlated', 'correlated2', 'restr', 'ROMM', 'out-dect' |
| ...       | see possible arguments below  |
| p         | multiplication factor for method 'ROMM'   |
| delta     | parameter for method 'correlated2', details can be found in the reference below.    |

## Details

If ‘obj’ is of class “sdcMicroObj” all continuous key variables are selected per default. If ‘obj’ is of class “data.frame” or “matrix”, the continuous variables have to be specified.

Method ‘additive’ adds noise completely at random to each variable depending on there size and standard deviation. ‘correlated’ and method ‘correlated2’ adds noise and preserves the covariances as described in R. Brand (2001) or in the reference given below. Method ‘restr’ takes the sample size into account when adding noise. Method ‘ROMM’ is an implementation of the algorithm ROMM (Random Orthogonalized Matrix Masking) (Fienberg, 2004). Method ‘outdetect’ adds noise only to outliers. The outliers are identified with univariate and robust multivariate procedures based on a robust mahalanobis distances calculated by the MCD estimator.

## Value

If ‘obj’ was of class “sdcMicroObj” the corresponding slots are filled, like manipNumVars, risk and utility.

If ‘obj’ was of class “data.frame” or “matrix” an object of class “micro” with following entities is returned:

|        |                               |
|--------|-------------------------------|
| x      | the original data             |
| xm     | the modified (perturbed) data |
| method | method used for perturbation  |
| noise  | amount of noise               |

## Methods

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

## Author(s)

Matthias Templ

### Examples

```
data(Tarragona)
a1 <- addNoise(Tarragona)
a1

data(testdata)
testdata[, c('expend', 'income', 'savings')] <-
addNoise(testdata[,c('expend', 'income', 'savings')])$xm

## for objects of class sdcMicroObj:
data(testdata2)
sdc <- createSdcObj(testdata2,
  keyVars=c('urbrur', 'roof', 'walls', 'water', 'electcon', 'relat', 'sex'),
  numVars=c('expend', 'income', 'savings'), w='sampling_weight')
sdc <- addNoise(sdc)
```

---

calcRisks

*Recompute Risk and Frequencies for a sdcMicroObj*

---

### Description

Recomputation of Risk should be done after manual changing the content of an object of class 'sdcMicroObj'

### Usage

```
calcRisks(obj,...)
```

### Arguments

|     |                                  |
|-----|----------------------------------|
| obj | an object of class 'sdcMicroObj' |
| ... | no arguments at the moment       |

## Details

By applying this function, the disclosure risk is re-estimated and the corresponding slots of an object of class “sdcMicro” are updated. This function mostly used internally to automatically update the risk after an sdc method is applied.

## Methods

```
signature(obj = "sdcMicroObj")
```

## See Also

[sdcMicroObj-class](#)

## Examples

```
data(testdata2)
sdc <- createSdcObj(testdata2,
  keyVars=c('urbrur','roof','walls','water','electcon','relat','sex'),
  numVars=c('expend','income','savings'), w='sampling_weight')
sdc <- calcRisks(sdc)
```

---

casc1

*Small Artificial Data set*

---

## Description

Small Toy Example Data set which was used by Sanz-Mateo et.al.

## Usage

```
data(casc1)
```

## Format

The format is: int [1:13, 1:7] 10 12 17 21 9 12 12 14 13 15 ... - attr(\*, "dimnames")=List of 2 ..\$ : chr [1:13] "1" "2" "3" "4" ... ..\$ : chr [1:7] "1" "2" "3" "4" ...

## Examples

```
data(casc1)
casc1
```

|--------------------|------------------------|
| CASCrefermicrodata | <i>Census data set</i> |
|--------------------|------------------------|

---

**Description**

This test data set was obtained on July 27, 2000 using the public use Data Extraction System of the U.S. Bureau of the Census.

**Usage**

```
data(CASCrefermicrodata)
```

**Format**

A data frame sampled from year 1995 with 1080 observations on the following 13 variables.

AFNLWGT Final weight (2 implied decimal places)  
AGI Adjusted gross income  
EMCONTRB Employer contribution for hlth insurance  
FEDTAX Federal income tax liability  
PTOTVAL Total person income  
STATETAX State income tax liability  
TAXINC Taxable income amount  
POTHVAL Total other persons income  
INTVAL Amt of interest income  
PEARNVAL Total person earnings  
FICA Soc. sec. retirement payroll deduction  
WSALVAL Amount: Total Wage and salary  
ERNVAL Business or Farm net earnings

**Source**

Public use file from the CASC project. More information on this test data can be found in the paper listed below.

---

**Description**

Fast generation of (primitive) synthetic multivariate normal data.

**Usage**

```
dataGen(obj,...)# n = 200)
```

**Arguments**

|     |   |
|-----|---|
| obj | data.frame or matrix                          |
| ... | see possible arguments below                  |
| n   | amount of observations for the generated data |

**Details**

Uses the cholesky decomposition to generate synthetic data with approx. the same means and covariances. For details see at the reference.

**Value**

the generated synthetic data.

**Methods**

```
signature(obj = "data.frame")  
signature(obj = "matrix")  
signature(obj = "sdcMicroObj")
```

**Note**

With this method only multivariate normal distributed data with approximately the same covariance as the original data can be generated without reflecting the distribution of real complex data, which are, in general, not follows a multivariate normal distribution.

|-------|--------------------------------|
| dRisk | <i>overall disclosure risk</i> |
|-------|--------------------------------|

---

Description

Distance-based disclosure risk estimation via standard deviation-based intervals around observations.

Usage

```
dRisk(obj,...)# xm, k = 0.05)
```

Arguments

|     |  |
|-----|--|
| obj | original data or object of class sdcMicroObj |
| ... | see possible arguments below                 |
| xm  | perturbed data                               |
| k   | percentage of the standard deviation         |

Details

An interval (based on the standard deviation) is built around each value of the perturbed value. Then we look if the original values lay in these intervals or not. With parameter k one can enlarge or down scale the interval.

Value

The disclosure risk or/and the modified “sdcMicroObj”

**Methods**

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

---

dRiskRMD

*RMD based disclosure risk*

---

**Description**

Distance-based disclosure risk estimation via robust Mahalanobis Distances.

**Usage**

```
dRiskRMD(obj,...)#xm, k = 0.01, k2=0.05)
```

## Arguments

|     |   |
|-----|---|
| obj | original data or object of class <code>sdcMicroObj</code>   |
| ... | see possible arguments below  |
| xm  | masked data   |
| k   | weight for adjusting the influence of the robust Mahalanobis distances, i.e. to increase or decrease each of the disclosure risk intervals. |
| k2  | parameter for method RMDID2 to choose a small interval around each masked observation.  |

## Details

This method is an extension of method SDID because it accounts for the “outlyingness” of each observations. This is a quite natural approach since outliers do have a higher risk of re-identification and therefore these outliers should have larger disclosure risk intervals as observations in the center of the data cloud.

The algorithm works as follows:

1. Robust Mahalanobis distances are estimated in order to get a robust multivariate distance for each observation.
2. Intervals are estimated for each observation around every data point of the original data points where the length of the interval is defined/weighted by the squared robust Mahalanobis distance and the parameter `$k$`. The higher the RMD of an observation the larger the interval.
3. Check if the corresponding masked values fall into the intervals around the original values or not. If the value of the corresponding observation is within such an interval the whole observation is considered unsafe. So, we get a whole vector indicating which observation is save or not, and we are finished already when using method RMDID1).
4. For method RMDID1w: we return the weighted (via RMD) vector of disclosure risk.
5. For method RMDID2: whenever an observation is considered unsafe it is checked if `$m$` other observations from the masked data are very close (defined by a parameter `$k2$` for the length of the intervals as for SDID or RSDID) to such an unsafe observation from the masked data, using Euclidean distances. If more than `$m$` points are in such a small interval, we conclude that this observation is “save”.

## Value

The disclosure risk or the modified “`sdcMicroObj`”

|            |  |
|------------|--|
| risk1      | percentage of sensitive observations according to method RMDID1.   |
| risk2      | standardized version of risk1  |
| wrisk1     | amount of sensitive observations according to RMDID1 weighted by their corresponding robust Mahalanobis distances. |
| wrisk2     | RMDID2 measure   |
| indexRisk1 | index of observations with high risk according to risk1 measure  |
| indexRisk2 | index of observations with high risk according to wrisk2 measure   |

**Methods**

```
signature(obj = "data.frame")  
signature(obj = "matrix")  
signature(obj = "sdcMicroObj")
```

dUtility

*data utility*

---

**Description**

IL1s data utility.

**Usage**

```
dUtility(obj,...)#, xm, method="IL1")
```

**Arguments**

|        |  |
|--------|--|
| obj    | original data or object of class sdcMicroObj                         |
| ...    | see arguments below  |
| xm     | perturbed data   |
| method | method IL1 or eigen. More methods are implemented in summary.micro() |

**Details**

The standardised distances of the perturbed data values to the original ones are measured. Measure IL1 measures the distances between the original values and the perturbed ones, scaled by the standard deviation. Method ‘eigen’ and ‘robeigen’ compares the eigenvalues and robust eigenvalues from the original data and the perturbed data.

**Value**

data utility or modified entry for data utility the “sdcMicroObj”.

**Methods**

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

|----------|-----------------------------------|

---

**Description**

Small synthetic data from Capobianchi, Poletti, Lucarelli

**Usage**

```
data(francdat)
```

**Format**

A data frame with 8 observations on the following 8 variables.

Num1 a numeric vector

Key1 Key variable 1. A numeric vector

Num2 a numeric vector

Key2 Key variable 2. A numeric vector

Key3 Key variable 3. A numeric vector

Key4 Key variable 4. A numeric vector

Num3 a numeric vector

w The weight vector. A numeric vector

**Details**

This data set is very similar to that one which are used by the authors of the paper given below. We need this data set only for demonstration effect, i.e. that the package provides the same results as their software.

freq-methods

*Print and Extractor Functions for objects of class 'sdcMicroObj'*

---

### Description

Descriptive print function for Frequencies, local Supression, Recoding, categorical risk and numerical risk.

### Usage

```
print(x,...)
freq(obj,type="fk")
```

**Arguments**

|      |   |
|------|---|
| x    | An object of class 'sdcMicroObj'                    |
| obj  | An object of class 'sdcMicroObj'                    |
| type | Selection of the content to be returned or printed- |
| ...  | the type argument for the print method              |

**Details**

Possible values for the type argument of the print function are: "freq": for Frequencies, "ls": for Local Supression output, "pram": for results of post-randomization "recode":for Recodes, "risk": forCategorical risk and "numrisk": for Numerical risk.

Possible values for the type argument of the freq function are: "fk": Sample frequencies and "Fk": weighted frequencies.

**Author(s)**

Alexander Kowarik, Matthias Templ

**Examples**

```
data(testdata)
sdc <- createSdcObj(testdata,
  keyVars=c('urbrur','roof','walls','relat','sex'),
  pramVars=c('water','electcon'),
  numVars=c('expend','income','savings'), w='sampling_weight')
fk=freq(sdc)
Fk=freq(sdc,type="Fk")
print(sdc)
print(sdc,type="ls")
print(sdc,type="recode")
print(sdc,type="risk")
print(sdc,type="numrisk")
print(sdc,type="pram")
```

---

freqCalc

*Frequencies calculation for risk estimation*

---

**Description**

Computation and estimation of the sample and population frequency counts.

**Usage**

```
freqCalc(x, keyVars, w = NULL, fast=TRUE)
```

**Arguments**

|         |   |
|---------|---|
| x       | data frame or matrix  |
| keyVars | key variables   |
| w       | column index of the weight variable. Should be set to NULL if one deal with a population. |
| fast    | beta version of faster algorithm should not change the results in any way                 |

**Details**

The function considers the case of missing values in the data. A missing value stands for any of the possible categories of the variable considered. It is possible to apply this function to large data sets with many (categorical) key variables, since the computation is done in C.

*freqCalc()* does not support *sdcmicro* S4 class objects.

**Value**

Object from class *freqCalc*.

|          |  |
|----------|--|
| freqCalc | data   |
| keyVars  | keyVars  |
| w        | index of weight vector. NULL if you do not have a sample.  |
| indexG   |  |
| fk       | the frequency of equal observations in the key variables subset sample given for each observation. |
| Fk       | estimated frequency in the population  |
| n1       | amount of observations with fk=1   |
| n2       | amount of observations with fk=2   |

```

---

generateStrata

---

*Generate one strata variable from multiple factors*

---

**Description**

For strata defined by multiple variables (e.g. sex,age,country) one combined variable is generated.

**Usage**

```
generateStrata(df, stratavars, name)
```

**Arguments**

|            |                                      |
|------------|--------------------------------------|
| df         | a data.frame                         |
| stratavars | character vector with variable name  |
| name       | name of the newly generated variable |

**Value**

The original data set with one new column.

**Author(s)**

Alexander Kowarik

**Examples**

```
x <- testdata
x <- generateStrata(x,c("sex","urbrur"),"strataIDvar")
head(x)
```

globalRecode

*Global Recoding***Description**

Global recoding

**Usage**

```
globalRecode(obj,...)#, column,breaks, labels, method="equidistant")
```

**Arguments**

|        |   |
|--------|---|
| obj    | vector of class numeric or of class factor with integer labels for recoding or an object of class <code>sdcMicroObj</code>  |
| column | which keyVar should be changed  |
| ...    | see possible arguments below  |
| breaks | either a numeric vector of cut points or number giving the number of intervals which x is to be cut into.   |
| labels | labels for the levels of the resulting category. By default, labels are constructed using "(a,b]" interval notation. If labels = FALSE, simple integer codes are returned instead of a factor.                    |
| method | method "equidistant" for equal sized intervalls<br>method "logEqui" for equal sized intervalls for log-transformed data<br>method "equalAmount" for intervalls with approximately the same amount of observations |

**Details**

If a labels parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed.

**Value**

the modified "sdcMicroObj" or a factor, unless labels = FALSE which results in the mere integer level codes.

**Methods**

```
signature(obj = "ANY")
signature(obj = "sdcMicroObj")
```

---

|           |   |
|-----------|---|
| groupVars | <i>Join levels of a keyVariable in an object of class 'sdcMicroObj'</i> |
|-----------|---|

---

Description

Transforms the factor variable into a factors with less levels and recomputes risk.

Usage

```
groupVars(obj, var, before, after)
```

Arguments

|        |                                   |
|--------|-----------------------------------|
| obj    | object of class 'sdcMicroObj'     |
| var    | name of the keyVariable to change |
| before | vector of levels before           |
| after  | vector of levels after            |

Value

the modified "sdcMicroObj"

Methods

```
signature(obj = "sdcMicroObj")
```

## Examples

sdc <- groupVars(sdc, var="urbrur", before=c(1,2), after=1)
```

---

indivRisk

*Individual Risk computation*

---

## Description

Individual risk computation.

## Usage

```
indivRisk(x, method = "approx", qual = 1, survey=TRUE)
```

## Arguments

|        |  |
|--------|--|
| x      | object from class freqCalc   |
| method | approx (default) or exact  |
| qual   | final correction factor  |
| survey | TRUE, if one have survey data and FALSE if one deal with the whole population. |

## Details

Estimation of the risk for each observation. After the risk is computed one can use e.g. the function `localSuppr()` for the protection of values of high risk. Further details can be found at the link given below.

S4 class `sdcMicro` objects are only supported by function *measure\_risk* that also estimates the individual risk with the same method.

## Value

|        |                               |
|--------|-------------------------------|
| rk     | base individual risk          |
| method | method                        |
| qual   | final correction factor       |
| fk     | frequency count               |
| knames | colnames of the key variables |

**Note**

The base individual risk method was developed by Benedetti, Capobianchi and Franconi

LLmodGlobalRisk

*Global risk using log-linear models.*

---

**Description**

The sample frequencies are assumed to be independent and following a Poisson distribution. The parameters of the corresponding parameters are estimated by a log-linear model including the main effects and possible interactions.

**Usage**

```
LLmodGlobalRisk(obj, method = "IPF", inclProb = NULL, form = NULL, modOutput = FALSE)
```

**Arguments**

|           |   |
|-----------|---|
| obj       | An object of class <code>sdcMicroObj</code> or a numeric matrix or data frame containing the categorical key variables. |
| method    | At this time, only iterative proportional fitting (“IPF”) can be used.  |
| inclProb  | Inclusion probabilities (experimental)  |
| form      | A formula specifying the model.   |
| modOutput | If TRUE, additional output is given.  |

**Details**

This measure aims to (1) calculate the number of sample uniques that are population uniques with a probabilistic Poisson model and (2) to estimate the expected number of correct matches for sample uniques.

ad 1) this risk measure is defined over all sample uniques (SU) as

$$\tau_1 = \sum_{SU} P(F_k = 1 | f_k = 1) \quad ,$$

i.e. the expected number of sample uniques that are population uniques.

ad 2) this risk measure is defined over all sample uniques (SU) as

$$\tau_2 = \sum_{SU} P(F_k = 1 | f_k = 1) \quad , CORRECT!$$

Since population frequencies  $F_k$  are unknown, they has to be estimated.

The iterative proportional fitting method is used to fit the parameters of the Poisson distributed frequency counts related to the model specified to fit the frequency counts. The obtained parameters are used to estimate a global risk, defined in Skinner and Holmes (1998).

**Value**

Two global risk measures or the modified risk in the “`sdcMicroObj`” object.

---

LocalRecProg

*Local recoding via Edmond's maximum weighted matching algorithm*

---

## Description

To be used on both categorical and numeric input variables, although usage on categorical variables is the focus of the development of this software.

Each record in the data represents a category of the original data, and hence all records in the input data should be unique by the N Input Variables. To achieve bigger category sizes (k-anonymity), one can form new categories based on the recoding result and repeatedly apply this algorithm.

## Usage

```
LocalRecProg(obj,ancestors=NULL,ancestor_setting=NULL,
  k_level=2, FindLowestK=TRUE, weight=NULL, lowMemory=FALSE, missingValue=NA,...)
  #,categorical,numerical=NULL
```

## Arguments

|                  |   |
|------------------|---|
| obj              | Input data or object of class sdcMicroObj   |
| ancestors        | Names of ancestors of the cateorical variables  |
| ancestor_setting | For each ancestor the corresponding categorical variable                                      |
| k_level          | Level for k-anonymity   |
| FindLowestK      | requests the program to look for the smallest k that results in complete matches of the data. |
| weight           | A weight for each variable (Default=1)  |
| lowMemory        | Slower algorithm with less memory consumption   |
| missingValue     | The output value for a suppressed value.  |
| ...              | see arguments below   |
| categorical      | Names of categorical variables  |
| numerical        | Names of numerical variables  |

**Value**

dataframe with original variables and the suppressed variables (suffix \_lr). / the modified “sdcMicroObj”

**Methods**

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")

---

localSupp

*Local Suppression*

---

**Description**

A simple method to perform local suppression.

**Usage**

```
localSupp(obj, threshold=0.15, keyVar,...)# indivRisk)
```

**Arguments**

|           |   |
|-----------|---|
| obj       | object of class freqCalc or sdcMicroObj           |
| threshold | threshold for individual risk                     |
| keyVar    | Variable on which some values might be suppressed |
| ...       | see arguments below                               |
| indivRisk | object from class indivRisk                       |

**Details**

Values of high risk (above the threshold) of a certain variable (parameter keyVar) are suppressed.

**Value**

Manipulated data with suppressions or the “sdcMicroObj” object with manipulated data.

**Methods**

```
signature(obj = "ANY")  
signature(obj = "sdcMicroObj")
```

```

---

localSupp2

*Local Suppression 2*

---

### Description

An Algorithm to perform local suppression to achieve k-anonymity.

### Usage

```
localSupp2(x, keyVars, w, importance=rep(1, length(keyVars)),
  method="minimizeSupp", k=1)
```

### Arguments

|            |  |
|------------|--|
| x          | data frame or matrix   |
| keyVars    | column index of key variables  |
| w          | column index of sampling weights   |
| importance | weights for each key variable  |
| method     | “minimizeSupp” (default), further methods will be included in future versions of the package |
| k          | parameter for k-anonymity.   |

### Details

With the help of this algorithm you can achieve k-anonymity in an optimized way. The procedure set missings only to those key variables for which the importance is greater than 0. Key variables with higher importance will be preferred to be the variable which will be used for suppression of specific values, i.e. the vector of importance assign to each key variable a weight which is considered by the algorithm.

To guarantee k-anonymity the wrapper of function localSupp2 should be applied (localSupp2Wrapper())

However, if the importance of some key variables are equal to zero, the algorithm may not find a k-anonymity solution (because there isn't any solution reachable at all, for example). The easiest way to overcome this situation is to re-run the algorithm and allow for NA's in some more key variables, i.e. re-run the algorithm with importance greater than 0 for all entries of importance. This will result in k-anonymized results and leads to only few suppressions in the key variables where the importance of the variables are considered.

Method fastSupp avoids some calculation steps but this method is only significant faster if there is a large data sets with few key variables. However, fastSupp leads to an oversuppression (slightly).

### Value

Object from class localSupp2.

|            |   |
|------------|---|
| xAnon      | resulting data with suppressions            |
| supps      | number of suppressions in the key variables |
| totalSupps | total number of suppressions.               |
| anonymity  | TRUE, if k-anonymity is achieved            |
| keyVars    | index of the key variables.                 |
| importance | weight vector for key variables             |
| k          | k for k-anonymity                           |

### Note

fix me: Implementation in C and interface to R.

```

---

|                   |                            |
|-------------------|----------------------------|
| localSupp2Wrapper | <i>Local Suppression 2</i> |
|-------------------|----------------------------|

---

### Description

A wrapper function for function localSupp2 in order to guarantee k-anonymity.

### Usage

```
localSupp2Wrapper(x, keyVars, w, importance=rep(1, length(keyVars)),
method="minimizeSupp", kAnon=2)
```

### Arguments

|            |  |
|------------|--|
| x          | data frame or matrix   |
| keyVars    | column index of key variables  |
| w          | column index of sampling weights   |
| importance | weights for each key variable, see 'localSupp2()'  |
| method     | "minimizeSupp" (default), further methods will be included in future versions of the package |
| kAnon      | parameter for k-anonymity.   |

### Details

This wrapper function guarantees k-anonymity. If function localSupp2() cannot reach k-anonymity, localSupp2 must be re-run on the previous results as long as k-anonymity is reached. If k-anonymity cannot be achieved (because the entries of parameter importance includes too much zeros) the function breaks after a sub-optimal solution is obtained.

### Value

Object from class localSupp2.

|            |   |
|------------|---|
| xAnon      | resulting data with suppressions            |
| supps      | number of suppressions in the key variables |
| totalSupps | total number of suppressions.               |
| anonymity  | TRUE, if k-anonymity is achieved            |
| keyVars    | index of the key variables.                 |
| importance | weight vector for key variables             |
| kAnon      | k for k-anonymity                           |

### Note

fix me: Implementation in C and interface to R.

print("this function is deprecated, please use localSuppression() instead")
```

---

|                  |  |
|------------------|--|
| localSuppression | <i>Local Suppression to obtain k-anonymity</i> |
|------------------|--|

---

**Description**

Algorithm to achieve k-anonymity by performing local suppression.

**Usage**

```
localSuppression(obj,k=2, importance=NULL,...)#, keyVars)
```

**Arguments**

|            |   |
|------------|---|
| obj        | an object of class sdcMicroObj or a data frame or matrix  |
| k          | threshold for k-anonymity   |
| importance | numeric vector of numbers between 1 and n (n=length of vector keyVars). This vector represents the "importance" of variables that should be used for local suppression in order to obtain k-anonymity. key-variables with importance=1 will - if possible - not suppressed, key-variables with importance=n will be used whenever possible. |
| ...        | see arguments below   |
| keyVars    | numeric vector specifying indices of (categorical) key-variables  |

**Details**

The algorithm provides a k-anonymized data set by suppressing values in key variables. The algorithm tries to find an optimal solution to suppress as few values as possible and considers the specified importance vector. If not specified, the importance vector is constructed in a way such that key variables with a high number of characteristics are considered less important than key variables with a low number of characteristics.

**Value**

Manipulated data set with suppressions that has k-anonymity with respect to specified key-variables or the manipulated data stored in the “sdcMicroObj” object.

**Methods**

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcmicroObj")
```

**Author(s)**

Bernhard Meindl, Matthias Templ

**Examples**

```
data(franccat)
## Local Suppression
localS <- localSuppression(franccat, keyVar=c(4,5,6))
localS
plot(localS)

## for objects of class sdcMicro:
data(testdata2)
sdcm <- createSdcObj(testdata2,
  keyVars=c('urbrur','roof','walls','water','electcon','relat','sex'),
  numVars=c('expend','income','savings'), w='sampling_weight')
sdcm <- localSuppression(sdcm)
```

---

mafast

*Fast and Simple Microaggregation*

---

**Description**

Function to perform a fast and simple (primitive) method of microaggregation. (for large datasets)

**Usage**

```
mafast(obj, variables=NULL, by=NULL, aggr=3, measure=mean)
```

**Arguments**

|           |   |
|-----------|---|
| obj       | either an object of class sdcMicroObj or a data frame or matrix   |
| variables | variables to microaggregate. If obj is of class sdcMicroObj the numerical key variables are chosen per default.     |
| by        | grouping variable for microaggregation. If obj is of class sdcMicroObj the strata variables are chosen per default. |
| aggr      | aggregation level (default=3)   |
| measure   | aggregation statistic, mean, median, trim, onestep (default = mean)   |

**Value**

If ‘obj’ was of class “sdcMicroObj” the corresponding slots are filled, like manipNumVars, risk and utility. If ‘obj’ was of class “data.frame” or “matrix” an object of the same class is returned.

**Methods**

```
signature(obj = "ANY")
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

---

measure\_risk

*Disclosure Risk for Categorical Variables*

---

## Description

The function measures the disclosure risk for weighted or unweighted data. It computes the individual risk (and household risk if reasonable) and the global risk. It also computes a risk threshold based on a global risk value.

To be used when risk of disclosure for individuals within a family is considered to be statistical independent.

Internally, function *freqCalc()* and *indivRisk* are used for estimation.

## Usage

```
measure_risk(obj,...)
#measure_risk(data,keyVars,w=NULL,missing=-999,
#hid=NULL,max_global_risk=.01,fast_hier=TRUE)
ldiversity(obj,ldiv_index,l_rekurs_c=2,missing=-999,...)
## S3 method for class 'measure_risk'
print(x, ...)
## S3 method for class 'ldiversity'
print(x, ...)
```

## Arguments

|                 |  |
|-----------------|--|
| obj             | Object of class “sdcmicroObjet”  |
| ...             | see arguments below  |
| data            | Input data, either a matrix or a data.frame.                             |
| keyVars         | Names of categorical key variables                                       |
| w               | name of variable containing sample weights                               |
| hid             | name of the clustering variable, e.g. the household ID                   |
| missing         | a integer value to be used as missing value in the C++ routine           |
| ldiv_index      | indices (or names) of the variables used for l-diversity                 |
| l_rekurs_c      | l-Diversity Constant   |
| x               | Output of measure_risk, measure_hier or measure_thres                    |
| max_global_risk | Maximal global risk for threshold computation                            |
| fast_hier       | If TRUE a fast approximation is computed if household data are provided. |

## Details

Measuring individual risk: The individual risk approach based on so-called super-population models. In such models population frequency counts are modeled given a certain distribution. The estimation procedure of sample frequency counts given the population frequency counts is modeled by assuming a negative binomial distribution. This is used for the estimation of the individual risk. The extensive theory can be found in Skinner (1998), the approximation formulas for the individual risk used is described in Franconi and Poletini (2004).

Measuring hierarchical risk: If “hid” - the index of variable holding information on the hierarchical cluster structures (e.g., individuals that are clustered in households) - is provided, the hierarchical risk is additionally estimated. Note that the risk of re-identifying an individual within a household may also affect the probability of disclosure of other members in the same household. Thus, the household or cluster-structure of the data must be taken into account when estimating disclosure risks. It is commonly assumed that the risk of re-identification of a household is the risk that at least one member of the household can be disclosed. Thus this probability can be simply estimated from individual risks as 1 minus the probability that no member of the household can be identified.

Global risk: The sum of the individual risks in the dataset gives the expected number of re-identifications that serves as measure of the global risk.

l-Diversity: If “ldiv\_index” is unequal to NULL, i.e. if the indices of sensible variables are specified, various measures for l-diversity are calculated. l-diversity is an extension of the well-known k-anonymity approach where also the uniqueness in sensible variables for each pattern spanned by the key variables are evaluated.

## Value

A modified “sdcMicroObj” object or a list with the following elements:

|                  |  |
|------------------|--|
| global_risk_ER   | expected number of re-identification.  |
| global_risk      | global risk (sum of individual risks).   |
| global_risk_pct  | global risk in percent.  |
| Res              | matrix with the risk, frequency in the sample and grossed-up frequency in the population (and the hierarchical risk) for each observation. |
| global_threshold | for a given max_global_risk the threshold for the risk of observations.  |
| max_global_risk  | the input max_global_risk of the function.   |
| hier_risk_ER     | expected number of re-identification with household structure.   |
| hier_risk        | global risk with household structure (sum of individual risks).  |
| hier_risk_pct    | global risk with household structure in percent.   |
| ldiverstiy       | Matrix with Distinct_Ldiversity, Entropy_Ldiversity and Recursive_Ldiversity for each sensitivity variable.                                |

## Methods

signature(obj = "data.frame") Method for object of class "data.frame"  
 signature(obj = "matrix") Method for object of class "matrix"  
 signature(obj = "sdcMicroObj") Method for object of S4 class "sdcMicroObj"

---

|                  |                         |
|------------------|-------------------------|
| microaggregation | <i>Microaggregation</i> |
|------------------|-------------------------|

---

## Description

Function to perform various methods of microaggregation.

## Usage

```
microaggregation(obj,variables=NULL,aggr=3,strata_variables=NULL,method="mdav",
  weights=NULL, nc = 8, clustermethod = "clara", opt = FALSE, measure = "mean",
  trim = 0, varsort = 1, transf = "log")
```

## Arguments

|                               |   |
|-------------------------------|---|
| <code>obj</code>              | either an object of class <code>sdcMicroObj</code> or a data frame or matrix  |
| <code>variables</code>        | variables to microaggregate. For <code>NULL</code> : If <code>obj</code> is of class <code>sdcMicroObj</code> the categorical key variables are chosen per default. For data.frames and matrices all columns are chosen per default.                            |
| <code>aggr</code>             | aggregation level (default=3)   |
| <code>strata_variables</code> | by-variables for applying microaggregation only within strata defined by the variables  |
| <code>method</code>           | pca, rmd, onedims, single, simple, clustpca, pppca, clustpppca, mdav, clustmcd-pca, influence, mcdpca   |
| <code>nc</code>               | number of cluster, if the chosen method performs cluster analysis   |
| <code>weights</code>          | sampling weights. If <code>obj</code> is of class <code>sdcMicroObj</code> the vector of sampling weights is chosen automatically. If determined, a weighted version of the aggregation measure is chosen automatically, e.g. weighted median or weighted mean. |

|               |   |
|---------------|---|
| clustermethod | clustermethod, if necessary   |
| opt           | experimental  |
| measure       | aggregation statistic, mean, median, trim, onestep (default = mean) |
| trim          | trimming percentage, if measure=trim                                |
| varsort       | variable for sorting, if method= single                             |
| transf        | transformation for data x   |

## Details

On <http://neon.vb.cbs.nl/casc/Glossary.htm> one can find the “official” definition of microaggregation:

Records are grouped based on a proximity measure of variables of interest, and the same small groups of records are used in calculating aggregates for those variables. The aggregates are released instead of the individual record values.

The recommended method is “rmd” which forms the proximity using multivariate distances based on robust methods. It is an extension of the well-known method “mdav”. However, when computational speed is important, method “mdav” is the preferable choice.

While for the proximity measure very different concepts can be used, the aggregation itself is naturally done with the arithmetic mean. Nevertheless, other measures of location can be used for aggregation, especially when the group size for aggregation has been taken higher than 3. Since the median seems to be unsuitable for microaggregation because of being highly robust, other measures which are included can be chosen. If a complex sample survey is microaggregated, the corresponding sampling weights should be determined to either aggregate the values by the weighted arithmetic mean or the weighted median.

This function contains also a method with which the data can be clustered with a variety of different clustering algorithms. Clustering observations before applying microaggregation might be useful. Note, that the data are automatically standardised before clustering.

The usage of clustering method ‘Mclust’ requires package mclust02, which must be loaded first. The package is not loaded automatically, since the package is not under GPL but comes with a different licence.

There are also some projection methods for microaggregation included. The robust version ‘pppca’ or ‘clustpppca’ (clustering at first) are fast implementations and provide almost everytime the best results.

Univariate statistics are preserved best with the individual ranking method (we called them ‘oned-ims’, however, often this method is named ‘individual ranking’), but multivariate statistics are strongly affected.

With method ‘simple’ one can apply microaggregation directly on the (unsorted) data. It is useful for the comparison with other methods as a benchmark, i.e. replies the question how much better is a sorting of the data before aggregation.

## Value

If ‘obj’ was of class “sdcMicroObj” the corresponding slots are filled, like manipNumVars, risk and utility. If ‘obj’ was of class “data.frame” or “matrix” an object of class “micro” with following entities is returned:

|         |  |
|---------|--|
| mx      | the aggregated data  |
| x       | original data  |
| method  | method   |
| aggr    | aggregation level  |
| measure | proximity measure for aggregation  |
| fot     | correction factor, necessary if totals calculated and n divided by aggr is not an integer. |

## Methods

```
signature(obj = "ANY")
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

## Author(s)

Matthias Templ

For method “mdav”: This work is being supported by the International Household Survey Network (IHSN) and funded by a DGF Grant provided by the World Bank to the PARIS21 Secretariat at the Organisation for Economic Co-operation and Development (OECD). This work builds on previous work which is elsewhere acknowledged.

Author for the integration of the code for mdav in R: Alexander Kowarik.

|----------------|---|
| microaggrGower | <i>Microaggregation for numerical and categorical key variables based on a distance similar to the GOWER DISTANCE</i> |
|----------------|---|

---

## Description

The microaggregation is based on the distances computed similar to the Gower distance. The distance function makes distinction between the variable types factor,ordered,numerical and mixed (semi-continuous variables with a fixed probability mass at a constant value e.g. 0)

## Usage

```
microaggrGower(obj, variables = NULL, aggr = 3, dist_var = NULL,
  by = NULL, mixed = NULL, mixed.constant = NULL, trace = FALSE,
  weights = NULL, numFun = mean, catFun = sampleCat, addRandom = FALSE)
sampleCat(x)
maxCat(x)
```

## Arguments

|                |   |
|----------------|---|
| obj            | an object of class sdcMicroObj or a data frame  |
| variables      | character vector with names of variables to be aggregated (Default for sdcMicroObj is all keyVariables and all numeric key variables) |
| aggr           | aggregation level (default=3)   |
| dist_var       | character vector with variable names for distance computation   |
| by             | character vector with variable names to split the dataset before performing microaggregation (Default for sdcMicroObj is strataVar)   |
| mixed          | character vector with names of mixed variables  |
| mixed.constant | numeric vector with length equal to mixed, where the mixed variables have the probability mass  |

|           |   |
|-----------|---|
| trace     | TRUE/FALSE for some console output  |
| weights   | numerical vector with length equal the number of variables for distance computation |
| numFun    | function: to be used to aggregated numerical variables                              |
| catFun    | function: to be used to aggregated categorical variables                            |
| addRandom | TRUE/FALS if a random value should be added for the distance computation.           |
| x         | a factor vector   |

### Details

The function `sampleCat` samples with probabilities corresponding to the occurrence of the level in the NNs. The function `maxCat` chooses the level with the most occurrences and random if the maximum is not unique.

### Value

The function returns the updated `sdcMicroObj` or simply an altered data frame.

### Note

In each by group all distance are computed, therefore introducing more by-groups significantly decreases the computation time and memory consumption.

### Author(s)

Alexander Kowarik

### Examples

```
data(testdata,package="sdcMicro")
testdata <- testdata[1:200,]
for(i in c(1:7,9)) testdata[,i] <- as.factor(testdata[,i])
test <- microaggrGower(testdata,variables=c("relat","age","expend"),
  dist_var=c("age","sex","income","savings"),by=c("urbrur","roof"))

sdc <- createSdcObj(testdata,
  keyVars=c('urbrur','roof','walls','water','electcon','relat','sex'),
  numVars=c('expend','income','savings'), w='sampling_weight')

sdc <- microaggrGower(sdc)
```

---

microData

*microData*

---

**Description**

Small artificial toy data set.

**Usage**

```
data(microData)
```

**Format**

The format is: num [1:13, 1:5] 5 7 2 1 7 8 12 3 15 4 ... - attr(\*, "dimnames")=List of 2 ..\$ : chr [1:13] "10000" "11000" "12000" "12100" ... ..\$ : chr [1:5] "one" "two" "three" "four" ...

**Examples**

```
data(microData)
m1 <- microaggregation(microData, method="mdav")
summary(m1)
```

---

plot.localSuppression *plot method for localSuppression objects*

---

**Description**

Barplot for objects from class localSuppression.

**Usage**

```
## S3 method for class 'localSuppression'
plot(x, ...)
```

**Arguments**

x                    object of class 'localSuppression'  
...                   Additional arguments passed through.

**Details**

Just look at the resulting plot.

**Author(s)**

Matthias Templ

**See Also**[localSuppression](#)**Examples**

```
## example from Capobianchi, Polettini and Lucarelli:
data(francdat)
l1 <- localSuppression(francdat, keyVars=c(2,4,5,6))
l1
plot(l1)
```

---

plotMicro*Comparison plots*

---

**Description**

Plots for the comparison of the original data and perturbed data.

**Usage**

```
plotMicro(x, p, which.plot = 1:3)
```

**Arguments**

|            |   |
|------------|---|
| x          | object from class micro   |
| p          | necessary parameter for the box cox transformation (lambda)                                     |
| which.plot | which plot should be created? 1: density traces, 2: parallel boxplots, 3: differences in totals |

**Details**

Univariate and multivariate comparison plots are implemented to detect differences between the perturbed and the original data, but also to compare perturbed data which are produced by different methods.

## Examples

```
data(free1)
m1 <- microaggregation(free1[, 31:34], method="onedims", aggr=3)
m2 <- microaggregation(free1[, 31:34], method="pca", aggr=3)
plotMicro(m1, 0.1, which.plot=1)
```

---

pram

*Post Randomization*

---

## Description

To be used on categorical data. It randomly change the values of variables on selected records (usually the risky ones) according to an invariant probability transition matrix.

## Usage

```
pram(obj, variables=NULL, strata_variables=NULL, pd=0.8, alpha=0.5)
## S3 method for class 'pram'
print(x, ...)
```

## Arguments

|                  |   |
|------------------|---|
| obj              | Input data. Allowed input data are objects of class 'matrix', 'data.frame', 'vector' or 'sdcMicroObj'.                                      |
| variables        | Names of variables in 'obj' on which post-randomization should be applied. If obj is a vector, this argument is ignored.                    |
| strata_variables | Names of variables for stratification (will be set automatically for an object of class 'sdcMicroObj')                                      |
| x                | Output of pram()  |
| ...              | further input, currently ignored.   |
| pd               | minimum diagonal entries for the generated transition matrix P. Either a vector of length 1 or a vector of length ( number of categories ). |
| alpha            | amount of perturbation for the invariant Pram method  |

## Value

a modified "sdcMicroObj" object or a new object containing original and post-randomized variables (with suffix "\_pram").

## Methods

```
signature(obj = "data.frame")
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
signature(obj = "ANY")
```

**Note**

The functionalities of pram\_strata and pram are merged into pram, therefore pram\_strata is deprecated.

|          |                      |
|----------|----------------------|
| rankSwap | <i>Rank Swapping</i> |
|----------|----------------------|

---

Description

Swapping values within a range so that, first, the correlation structure of original variables are preserved, and second, the values in each record are disturbed. To be used on numeric or ordinal variables where the rank can be determined and the correlation coefficient makes sense.

Usage

```
rankSwap(obj, variables=NULL,TopPercent=5,BottomPercent=5,
         K0=-1,R0=.95,P=0,missing=-999,seed=NULL)
```

Arguments

- obj object of class sdcMicroObj or matrix or data frame
- variables names or index of variables for that rank swapping is applied. For an object of class 'sdcMicroObj' all numeric key variables are selected if variables=NULL.
- TopPercent Percentage of largest values that are grouped together before rank swapping is applied.

|               |   |
|---------------|---|
| BottomPercent | Percentage of lowest values that are grouped together before rank swapping is applied.  |
| K0            | Subset-mean preservation factor. Preserves the means before and after rank swapping within a range based on K0. K0 is the subset-mean preservation factor such that $ X_1 - X_2  \leq \frac{2K_0 X_1}{\sqrt{(N_S)}}$ , where $X_1$ and $X_2$ are the subset means of the field before and after swapping, and $N_S$ is the sample size of the subset.           |
| R0            | Multivariate preservation factor. Preserves the correlation between variables within a certain range based on the given constant R0. We can specify the preservation factor as $R_0 = \frac{R_1}{R_2}$ where $R_1$ is the correlation coefficient of the two fields after swapping, and $R_2$ is the correlation coefficient of the two fields before swapping. |
| P             | Rank range as percentage of total sample size. We can specify the rank range itself directly, noted as $P$ , which is the percentage of the records. So two records are eligible for swapping if their ranks, $i$ and $j$ respectively, satisfy $ i - j  \leq \frac{PN}{100}$ , where $N$ is the total sample size.   |
| missing       | missig value code.  |
| seed          | Seed.   |

### Details

Rank swapping sorts the values of one numeric variable by their numerical values (ranking). The restricted range is determined by the rank of two swapped values, which cannot differ, by definition, by more than  $P$  percent of the total number of observations. R0 and K0 are only used if positive. Only one of the two are used (R0 is preferred if both are positive).

### Value

The rank-swapped data set or a modified “sdcMicroObj” object.

### Methods

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

### Author(s)

Alexander Kowarik for the interface.

For the underlying C++ code: This work is being supported by the International Household Survey Network (IHSN) and funded by a DGF Grant provided by the World Bank to the PARIS21 Secretariat at the Organisation for Economic Co-operation and Development (OECD). This work builds on previous work which is elsewhere acknowledged.

**Examples**

```
data(testdata2)
data_swap <- rankSwap(testdata2, variables=c("age", "income", "expend", "savings"))

## for objects of class sdcMicro:
data(testdata2)
sdc <- createSdcObj(testdata2,
  keyVars=c('urbrur', 'roof', 'walls', 'water', 'electcon', 'relat', 'sex'),
  numVars=c('expend', 'income', 'savings'), w='sampling_weight')
sdc <- rankSwap(sdc)
```

removeDirectID

*Remove certain variables from the data set inside a sdc object.***Description**

Delete variables without changing anything else in the sdcObject (writing NAs).

**Usage**

```
removeDirectID(obj, var)
```

**Arguments**

|     |                                      |
|-----|--------------------------------------|
| obj | object of class 'sdcMicroObj'        |
| var | name of the variable(s) to be remove |

**Value**

the modified "sdcMicroObj"

**Methods**

```
signature(obj = "sdcMicroObj")
```

**Author(s)**

Alexander Kowarik

**Examples**

```
## for objects of class sdcMicro:
data(testdata2)
sdc <- createSdcObj(testdata, keyVars=c('urbrur', 'roof'),
  numVars=c('expend', 'income', 'savings'), w='sampling_weight')
sdc <- removeDirectID(sdc, var="age")
```

---

|            |  |
|------------|--|
| renameVars | <i>Change the name of levels of a keyVariable in an object of class 'sd-cMicroObj'</i> |
|------------|--|

---

## Description

Change the labels of levels.

## Usage

```
renameVars(obj, var, before, after)
```

## Arguments

|        |                                   |
|--------|-----------------------------------|
| obj    | object of class 'sd-cMicroObj'    |
| var    | name of the keyVariable to change |
| before | vector of levels before           |
| after  | vector of levels after            |

## Value

the modified "sd-cMicroObj"

## Methods

```
signature(obj = "sd-cMicroObj")
```

  keyVars=c('urbrur','roof','walls','water','electcon','relat','sex'),
  numVars=c('expend','income','savings'), w='sampling_weight')
sdc <- renameVars(sdc, var="urbrur", before=2, after=78)
```

---

**report***Generate a HTML/LATEX output from an sdcMicroObj*

---

## Description

Summary statistics of the original and the perturbed data set

## Usage

```
report(obj, outdir=getwd(), filename="SDC-Report", format="HTML", title='SDC-Report',
       internal=FALSE)
```

## Arguments

|          |  |
|----------|--|
| obj      | an object of class 'sdcMicroObj' or 'reportObj'  |
| outdir   | output folder  |
| filename | output filename  |
| format   | HTML, TEXT or LATEX  |
| title    | Title for the report   |
| internal | TRUE/FALSE, if TRUE a detailed internal report is produced, else a non-disclosive overview |

## Details

The application of this function provides you with a html, text or pdf-report for your sdcMicro object that contains useful summaries about the anonymization process.

## Author(s)

Matthias Templ, Bernhard Meindl

## Examples

```
## Not run:

  numVars=c('expend', 'income', 'savings'), w='sampling_weight')
report(sdc)

## End(Not run)
```

---

sdcMicro-deprecated      *Deprecated Functions in sdcMicro Package*

---

**Description**

These functions are provided for compatibility with older versions of the **sdcMicro** package only, and may be removed eventually. Commands that worked in versions of the **sdcMicro** package prior to version 3.1.1 will not necessarily work in version 3.1.2 and beyond, or may not work in the same manner.

**Usage**

```
localSupp2(x, keyVars, w, importance=rep(1, length(keyVars)),
  method="minimizeSupp", k=1)
localSupp2Wrapper(x, keyVars, w, importance=rep(1, length(keyVars)),
  method="minimizeSupp", kAnon=2)
pram_strata(obj, variables=NULL, strata_variables=NULL, pd=0.8, alpha=0.5)
```

**Arguments**

|                  |   |
|------------------|---|
| x                | data frame or matrix  |
| keyVars          | column index of key variables   |
| w                | column index of sampling weights  |
| importance       | weights for each key variable   |
| method           | "minimizeSupp" (default), further methods will be included in future versions of the package  |
| k                | parameter for k-anonymity.  |
| kAnon            | parameter for k-anonymity.  |
| obj              | Input data. Allowed input data are objects of class 'matrix', 'data.frame', 'vector' or 'sdcMicroObj'.                                      |
| variables        | Names of variables in 'obj' on which post-randomization should be applied. If obj is a vector, this argument is ignored.                    |
| strata_variables | Names of variables for stratification (will be set automatically for an object of class 'sdcMicroObj')                                      |
| pd               | minimum diagonal entries for the generated transition matrix P. Either a vector of length 1 or a vector of length ( number of categories ). |
| alpha            | amount of perturbation for the invariant Pram method  |

**Details**

localSupp2 is now a synonym for [localSuppression](#). localSupp2Wrapper is now a synonym for [localSuppression](#).

---

|                   |                     |
|-------------------|---------------------|
| sdcMicroObj-class | Class "sdcMicroObj" |
|-------------------|---------------------|

---

### Description

Class to save all information about the SDC process

### Usage

```
createSdcObj(dat, keyVars, numVars = NULL, pramVars=NULL, weightVar = NULL, hhId = NULL,
  strataVar = NULL, sensibleVar=NULL, options = NULL)
undolast(obj)
nextSdcObj(obj)
show(object)
```

### Arguments

|             |   |
|-------------|---|
| dat         | The microdata set. A numeric matrix or data frame containing the data.                                |
| obj         | An object of class 'sdcMicroObj'  |
| object      | An object of class 'sdcMicroObj'  |
| keyVars     | Indices or names of categorical key variables. They must, of course, match with the columns of 'dat'. |
| pramVars    | Indices or names of categorical variables considered to be pramed.                                    |
| numVars     | Index or names of continuous key variables.   |
| weightVar   | Indices or name determining the vector of sampling weights.   |
| hhId        | Index or name of the cluster ID (if available).   |
| strataVar   | Indices or names of stratification variables.   |
| sensibleVar | Indices or names of sensible variables (for l-diversity)  |
| options     | additional options.   |

### Objects from the Class

Objects can be created by calls of the form `new("sdcMicroObj", ...)`.

### Slots

```
origData: Object of class "dataframeOrNULL" ~~
keyVars: Object of class "numericOrNULL" ~~
pramVars: Object of class "numericOrNULL" ~~
numVars: Object of class "numericOrNULL" ~~
weightVar: Object of class "numericOrNULL" ~~
hhId: Object of class "numericOrNULL" ~~

```

---

shuffle

*Shuffling and EGADP*

---

## Description

Data shuffling and General Additive Data Perturbation.

## Usage

```
shuffle(obj, form, method="ds", weights=NULL, covmethod="spearman",
  regmethod="lm", gadp=TRUE)
```

## Arguments

|                      |  |
|----------------------|--|
| <code>obj</code>     | An object of class <code>sdcMicroObj</code> or a <code>data.frame</code> including the data.   |
| <code>form</code>    | An object of class “formula” (or one that can be coerced to that class): a symbolic description of the model to be fitted. The responses have to consists of at least two variables of any class and the response variables have to be of class numeric. The response variables belongs to numeric key variables (quasi-identifiers of numeric scale). The predictors are can be distributed in any way (numeric, factor, ordered factor). |
| <code>method</code>  | currently either the original form of data shuffling (“ds” - default), “mvn” or “mlm”, see the details section. The last method is in experimental mode and almost untested.   |
| <code>weights</code> | Survey sampling weights. Automatically chosen when <code>obj</code> is of class “ <code>sdcMicroObj</code> ”.  |

|           |   |
|-----------|---|
| covmethod | Method for covariance estimation. “spearman”, “pearson” and “kendall” are possible. For the latter one, the implementation in package robustbase is used. |
| regmethod | Method for multivariate regression. “lm” and “MM” are possible. For method “MM”, the function “rlm” from package MASS is applied.                         |
| gadp      | TRUE, if the egadp results from a fit on the original data is returned.   |

### Details

Perturbed values for the sensitive variables are generated. The sensitive variables have to be stored as responses in the argument ‘form’, which is the usual formula interface for regression models in R.

For method “ds” the EGADP method is applied on the norm inverse percentiles. Shuffling then ranks the original values according to the GADP output. For further details, please see the references.

Method “mvn” uses a simplification and draws from the normal Copulas directly before these draws are shuffled.

Method “mlm” is also a simplification. A linear model is applied the expected values are used as the perturbed values before shuffling is applied.

### Value

If ‘obj’ is of class “sdcMicroObj” the corresponding slots are filled, like manipNumVars, risk and utility. If ‘obj’ is of class “data.frame” an object of class “micro” with following entities is returned:

|        |   |
|--------|---|
| shConf | the shuffled numeric key variables                      |
| egadp  | the perturbed (using gadp method) numeric key variables |

### Methods

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

### Note

In this version, the covariance method chosen is used for any covariance and correlation estimations in the whole gadp and shuffling function.

### Author(s)

Matthias Templ, Alexander Kowarik

  form=savings+expend ~ urbrur+walls)
```

---

suda2

*Suda2: Detecting Special Uniques*

---

## Description

SUDA risk measure for data from (stratified) simple random sampling.

## Usage

```
suda2(obj,...)#,variables=NULL,missing=-999,DisFraction=0.01)
```

**Arguments**

|                          |   |
|--------------------------|---|
| <code>obj</code>         | object of class “data.frame” or object of class “sdcMicroObj”   |
| <code>...</code>         | see arguments below   |
| <code>variables</code>   | Categorical (key) variables. Either the column names or and index of the variables to be used for risk measurement.                                 |
| <code>missing</code>     | Missing value coding in the given data set.   |
| <code>DisFraction</code> | It is the sampling fraction for the simple random sampling, and the common sampling fraction for stratified sampling. By default, it's set to 0.01. |

**Details**

Suda 2 is a recursive algorithm for finding Minimal Sample Uniques. The algorithm generates all possible variable subsets of defined categorical key variables and scans them for unique patterns in the subsets of variables. The lower the amount of variables needed to receive uniqueness, the higher the risk of the corresponding observation.

**Value**

A modified “sdcMicroObj” object or the following list

|                                  |   |
|----------------------------------|---|
| <code>ContributionPercent</code> | The contribution of each key variable to the SUDA score, calculated for each row. |
| <code>score</code>               | The suda score.   |
| <code>dissscore</code>           | The dis suda score  |

**Methods**

```
signature(obj = "data.frame")
signature(obj = "matrix")
signature(obj = "sdcMicroObj")
```

summary.pram*Summary method for objects from class pram*

---

**Description**

Summary method for objects from class ‘pram’ to provide information about transitions.

**Usage**

```
## S3 method for class 'pram'  
summary(object, ...)
```

**Arguments**

|        |                                      |
|--------|--------------------------------------|
| object | object from class ‘pram’             |
| ...    | Additional arguments passed through. |

**Details**

Shows various information about the transitions.

**Value**

The summary of object from class ‘pram’.

**Author(s)**

Matthias Templ

---

`swappNum`*Rank Swapping*

---

**Description**

Rank Swapping.

**Usage**

```
swappNum(x, w = 1:(dim(x)[2]), p)
```

**Arguments**

|                |   |
|----------------|---|
| <code>x</code> | matrix or data frame                                |
| <code>w</code> | variables, on which rank swapping should be applied |
| <code>p</code> | Percentage. Swapping range.                         |

**Details**

The values of a variable are ranked, then each ranked value is swapped with another ranked value randomly chosen within a restricted range, i.e. the rank of two swapped values cannot differ by more than  $p$  percent of the total number of records. The function apply the rank swapping on each variable independently.

**Value**

|                     |                            |
|---------------------|----------------------------|
| <code>x</code>      | original data              |
| <code>xm</code>     | the rank swapped data      |
| <code>method</code> | info about the method name |

---

swappNum-deprecated      *Rank Swapping*

---

**Description**

Rank Swapping.

**Usage**

```
swappNum(x, w = 1:(dim(x)[2]), p)
```

**Arguments**

|   |   |
|---|---|
| x | matrix or data frame                                |
| w | variables, on which rank swapping should be applied |
| p | Percentage. Swapping range.                         |

**Details**

The values of a variable are ranked, then each ranked value is swapped with another ranked value randomly chosen within a restricted range, i.e. the rank of two swapped values cannot differ by more than p percente of the total number of records. The function apply the rank swapping on each variable independently.

**Value**

Tarragona

*Tarragona data set*

---

**Description**

A real data set comprising figures of 834 companies in the Tarragona area. Data correspond to year 1995.

**Usage**

```
data(Tarragona)
```

**Format**

A data frame with 834 observations on the following 13 variables.

FIXED.ASSETS a numeric vector

CURRENT.ASSETS a numeric vector

TREASURY a numeric vector

UNCOMMITTED.FUNDS a numeric vector

PAID.UP.CAPITAL a numeric vector

SHORT.TERM.DEBT a numeric vector

SALES a numeric vector

LABOR.COSTS a numeric vector

DEPRECIATION a numeric vector

OPERATING.PROFIT a numeric vector

FINANCIAL.OUTCOME a numeric vector

GROSS.PROFIT a numeric vector

NET.PROFIT a numeric vector

**Source**

Public use data from the CASC project.

```

---

|          |   |
|----------|---|
| testdata | <i>A real-world data set on household income and expenditures</i> |
|----------|---|

---

**Description**

A concise (1-5 lines) description of the dataset.

**Usage**

```
data(testdata)
data(testdata2)
```

**Format**

A data frame with 4580 observations on the following 14 variables.

urbrur a numeric vector  
roof a numeric vector  
walls a numeric vector  
water a numeric vector  
electcon a numeric vector  
relat a numeric vector  
sex a numeric vector  
age a numeric vector  
hhcivil a numeric vector  
expend a numeric vector  
income a numeric vector  
savings a numeric vector  
ori\_hid a numeric vector  
sampling\_weight a numeric vector

A data frame with 93 observations on the following 19 variables.

urbrur a numeric vector  
roof a numeric vector  
walls a numeric vector  
water a numeric vector  
electcon a numeric vector  
relat a numeric vector  
sex a numeric vector  
age a numeric vector

hhcivil a numeric vector  
 expend a numeric vector  
 income a numeric vector  
 savings a numeric vector  
 ori\_hid a numeric vector  
 sampling\_weight a numeric vector  
 represent a numeric vector  
 category\_count a numeric vector  
 relat2 a numeric vector  
 water2 a numeric vector  
 water3 a numeric vector

```

---

topBotCoding

*Top and Bottom Coding*

---

## Description

Function for Top and Bottom Coding.

## Usage

```
topBotCoding(obj, value, replacement, kind = "top", column=NULL)
```

## Arguments

|             |   |
|-------------|---|
| obj         | vector or one-dimensional matrix or data.frame or object of class "sdcMicroObj" |
| value       | limit, from where it should be top- or bottom-coded                             |
| replacement | replacement value.  |
| kind        | top or bottom   |
| column      | xxx   |

## Details

Extreme values are replaced by one value to reduce the disclosure risk.

**Value**

Top or bottom coded data or modified “sdcMicroObj”.

**Methods**

```
signature(obj = "ANY")
signature(obj = "sdcMicroObj")
```

**Author(s)**

Matthias Templ

**See Also**

[indivRisk](#)

**Examples**

```
data(free1)
topBotCoding(free1[, "DEBTS"], value=9000, replacement=9100, kind="top")

## for objects of class sdcMicro:
data(testdata2)
sdc <- createSdcObj(testdata2, keyVars=c('urbrur', 'roof', 'walls', 'water', 'electcon', 'relat', 'sex'),
  numVars=c('expend', 'income', 'savings'), w='sampling_weight')
sdc <- topBotCoding(sdc, value=500000, replacement=1000, column="income")
testdataout <- extractManipData(sdc)
```

---

valTable

---

*Comparison of different microaggregation methods*

---

**Description**

A Function for the comparison of different perturbation methods.

**Usage**

```
valTable(x,
  method = c("simple", "onedims", "clustpppca", "addNoise: additive", "swappNum"),
  measure = "mean", clustermethod = "clara", aggr = 3, nc = 8,
  transf = "log", p=15, noise=15, w=1:dim(x)[2], delta=0.1)
```

## Arguments

|               |   |
|---------------|---|
| x             | data frame or matrix  |
| method        | microaggregation methods or adding noise methods or rank swapping.              |
| measure       | FUN for aggregation. Possible values are mean (default), median, trim, onestep. |
| clustermethod | clustermethod, if a method will need a clustering procedure                     |
| aggr          | aggregation level (default=3)   |
| nc            | number of clusters. Necessary, if a method will need a clustering procedure     |
| transf        | Transformation of variables before clustering.                                  |
| p             | Swapping range, if method swappNum has been chosen                              |
| noise         | noise addition, if an addNoise method has been chosen                           |
| w             | variables for swapping, if method swappNum has been chosen                      |
| delta         | parameter for adding noise method ‘correlated2’                                 |

## Details

Tabularise the output from summary.micro. Will be enhanced to all perturbation methods in future versions.

## Value

Measures of information loss splitted for the comparison of different methods.

Methods for adding noise should be named via “addNoise: method”, e.g. “addNoise: correlated”, i.e. the term ‘at first’ then followed by a ‘:’ and a blank and then followed by the name of the method as described in function ‘addNoise’.
